Project Name	Script-Controlled ACL – Restrict Record Access Based on Field Value
Maximum Marks	4 Marks

User Perspective: System Administrator / Security Compliance Officer

1. SAYS

- "Role-based access alone isn't granular enough to protect sensitive department-specific records."
- "Users from other departments shouldn't even see records assigned to EEE unless authorized."
- "We need dynamic security rules that inspect field values before granting read, write, create, or delete access."

2. THINKS

- *How can I enforce data isolation between departments without creating separate tables?*
- *Will custom scripts slow down database query performance or cause execution latency?*
- *Is there a clean way to ensure administrators maintain overriding access while restricting standard users?*

3. DOES

- Configures Access Control Lists (ACLs) using script conditions in ServiceNow.
- Tests permissions by impersonating different user roles (bb1, bb2, bb3, bb4, admin).
- Reviews database logs and access errors to verify that unauthorized queries are properly blocked.

4. FEELS

- **Frustrated** when standard out-of-the-box role checks leak unauthorized records across departments.
- **Anxious** about potential security breaches or compliance failures during audits.
- **Confident** once a dynamic, script-controlled ACL passes automated validation and enforces true row-level security.

5. PAINS

- Security vulnerabilities caused by overly broad default read permissions.

- Complexity in maintaining multiple script conditions across Create, Read, Write, and Delete operations.
- Risk of locking out legitimate users or breaking platform functionality if ACL scripts fail.

6. GAINS

- Automated, field-value-based data filtering across all list and form views.
- Centralized governance meeting 100% security compliance requirements.
- Enhanced data privacy without duplicating database tables or schemas.
